## DESCRIPTION OF NEW TASMANIAN SHELLS.

By the Rev. J. E. Tenison Woods, F.L.S., F.G.S.

[Read 8th November, 1875.]
The following marine shells have been placed at my disposal for description by Mr. W. Legrand, of Hobart Town, and the Rev. H. D. Atkinson. Mr. Legrand, who has one of the finest collections of shells in the southern hemisphere, has been a collector for years, and has become thoroughly familiar with the marine fauna of our coast. Mr. Atkinson has occupied himself with dredging for some years, and has been the only conchologist who has sought for novelties in that way in Tasmania. He has also been indefatigable in his efforts to advance the success of conchology in the Island, and it is owing to his efforts alone that some of the very interesting species here described have been brought to light. I also observed two new species from a small collection placed in my hands by Mr. Justiu Browne and the Curator of the Museum, Mr. Roblin. To all these gentlemen I take this opportunity to return my thanks.

In this list the measurements are always the greatest length, width, or height, as the case may be. In bivalves length means in every case from the umbones to the margin; width the greatest measurement in the opposite direction; and height the thickness of both valves united. All dimensions in French millimetres.
Pisania tasmanica n. s. P. $t$. fusiformi-elongata, alba, nitente, livis transversalibus subtillissimis, plicisque minutis, rotundatis, subdistantibus, creberrime cancellata; anfiactibus 7, convexis, declivis, ad suturam constrictis, varicibus ebnmeis, sub-obsoletis, ornatis ; apertura ovali, labro eburnco, incrassato; labio vix calloso. Long. 20. Lat. 7. Aper long. 7.
P. shell fusiformly elongate, white, shining, very thickly cancellate, with very fine transverse liræ and small rounded, subdistant plaits; whorls 7, convex, sloping, constricted at the suture, ornamented with ivory white sub-obsolete varices; aperture ovate, outer lip ivory white, thickened; inner lip scarcely callous.

Rarc, D'Entrecasteaux Channel. It was not without difficulty that I separated this species from $P$. reticulata, which it resembles in every respect, except that it is very much smaller, shining white, with two or three regular varices on each whorl. There are no varices in P. reticulata, and none are noticed by A. Adams (Zool. Proc. 1854, p. 138, sp. 39), whose description is hardly sufficiently detailed. In old spesimens of that shell the cancellated structure causes the plaits to be very granular, and it is a dull shell of a purple
brown color, but young specimens are more livid, and faintly banded with chestnut.

Purpera litt orinoidis, n.s. $P$. $t$. acuminuto-ovata, viridescenti allue ; spire clata, acnminata, mamillate ; anfractibus 6, angulatis et supra bicarinatis, liris ticenservelilnus, rotumetis (interstitios aquantibus) et squamatis, lamellis longitulinalibus, imbricatis cuncellatis; upertura acheté orutu, intus utro-violascente tincta; labio sub-planato, partim atro-ciolacea cneausto ; labro vici crenato. Long. 15. Lat. 8 .
P. shell acuminately ovate, greenish white, spire produced acuminate, mamillate; whorls 6 , angulate and bicarinate above, with tranverse rounded liræ (equalling the interstices in width), and cancellated with scaly imbricate lamelle ; aperture acutely ovate, stained deep blackish purple within; inner lip somewhat flattened and partly enamelled, blackish purple ; outer lip slightly crenulate. Long Bay, Southport, common.

This shell approaches in habit the $P$. Flindersi of Adams, and Angas, but it is much smaller and more like a Littorina, while the other resembles a Trophon. Its deep violet black mouth is very characteristic. P. Flindersi has a violet mouth, but very much paler and clouded.

Trophon umbilicatus, n.s. T. t. ovata, lutea rel pallide castanea, solida; spira eluta, anfrue 5-6, superne angulatis et concavis, conspicue longitudinaliter plicatis (ult. anfi. S) et transversim conferte liratis, liris magnis et parvis altermantibus, maynis planatis, et supra plicas squamato-imbricatis; squamis post columellam vatidis, elevatis, canaliculatisque; ad sutures costis lirisque obsoletis; labro extus crenato intus dentato ; labio columellari expanso; umbilico squamis imbricatis, rotunlatis marginato. Long. 27. Lat. 15.
T. shell ovate, yellow or pale chestnut, solid, spire raised; whorls 5-6, angulate above and concave, conspicuously plicate lengthwise ( 8 in the last), and transversely thickly lirate, liræ alternating large and small, the larger flattened, squamately imbricated over the plaits; squamæ behind the columella valid, raised and canaliculate; at the sutures, the plaits and liræ obsolete; outer lip crenulate outside and toothed within; columella lip expanded, umbilicus margined with rounded imbricated seales.

Rather uncommon, East Coast. At one time I considered this a Tasmanian variety of T. Hanleyi, Ang. but a comparison of many specimens shows me that the present is an entirely different shell, very much more scabrous. Tie umbilicus and its margin are also peculiar and distinct.
Trophon clathratus, n.s. T. t. parra, fusiformi, turrita, fulva; spivira ucuminata; unfractibus 8 , convexis, dcclicibus, validis, longitudinaliter costutis, costis rotundatis, subdistentibus, liris distentibus, cleratis, cluthrutis; apertura lata, intense rufo fulva (fasciata?), lubro temii ; canuli subelongata recurro. Long. 9. Lat. 4.
T. shell small fusiform, turretted, brownish; spire acu-
minate ; whorls 8, couvex, sloping, validly ribbed lengthwise, with rounded sub-distant ribs, and latticed with e'evated distant liræ; aperture wide, of deep reddish brown (doubtfully banded) ; outer lip thin, canal subelongate and recurved.

Rare, Bass Straits? A small very conspicuously latticed and turretted shell, in every way distinct from those previously described, which have no valid transverse liræ. It might be mistaken for a Clathurella, but that it has a true Trophon mouth and canal.
Trophon brazieri, n.s. T.t. parva, ovata, fusiformi, utrinque attenuata, soride alba, spiva subturrita, quasi acuta, mamillata, anfractibus 7 , costulato-varicosis, levigatis vel tenuissime striatis, ultimo anfractu varicibus sex, rotundatis, distantibus, medio convexis; apertrra ovata, encausta, fauce castarea, labio tenui, intus indistincte spiraliter fulvo-fasciata; columella antice subtuberculato; canuli subelongato recurvo. Long. 10. Lat. 5 mil.
T. shell small, ovately fusiform, attenuate at both ends, sordidl5 white, spire sub-turretted, almost acute, mamillate; whorls 7, with rib-like varices, smooth or finely striate, last whorl with six, rounded, distant varices, which are convex in the middle, aperture ovate, enamelled; mouth chestnut; outer lip thin, indistinctly brown banded within; columella subtuberculate anteriorly ; canal sub-elongate, recurved.

Long Bay, rather common, small, the enamelled chestnut mouth and narrow form easily distinguish it.
Trophon goldsteini. T'.t. abbreviato-fusiformi, lamelloso-varicosa, sordide alba, spira subturrita ; anfractibus 8 , convexis, superné angulatis'et coronatis, liris substantibus, subelevatis (ult. anfrac. 4, duobus lasim versus inter varices obsoletis), transversim cinctis; liris supra varices non transeuntibus; varicibus antice squamosis, flexuosis; apertura ovata, intus encausta, castanea et fulvo-fasciata; labro varicoso ; columella contorta ; canali contorto et flextuso. Long. 16. Lat. 8 mil.
T. shell abbreviately fusiform, lamellosely varicose, sordidly white, spire sub-turretted; whorls 8 , convex, angulate and coronate above, girdled transversely with distant sub-raised liræ (in last whorl 4, the two towards the base between the varices obsolete), liræ not passing over the varices, which are anteriorly squamose and flexuous; aperture ovate, enamelled and chestnut brown banded within; outer lip varicose ; columella twisted ; canal twisted and flexuous.

Long Bay, a very pretty lamellose Trophon which I have dedicated to an old and most painstaking fellow labourer in Australian Conchology, Mr. J. R. Y. Goldstein, of Warnambool, Victoria.

Trophon australis, n.s., T.t. ovata, utrinque acuminata, sordida, viridescenti: anfractibus 6 , convexis superne angulatis, obsolete long. costatis; et transucrsim temiter liratis; ultimo anfractu costis 10,
antice evanidis; spira acuta; apertura orata; labro tenui; columellu plenata; canuli longiusculo paulatim recurvo. Long. 16. Lat. 9.
T. shell ovate, acmminate at each end, sordidly greenish ; whorls 6, convex, angular above, obsoletely ribbed lengthways, and finely tranversely lirate; ribs on last whorl 10 , vauishing anteriorly; spire acute; aperture ovate, outer lip thin; columeltia flattened; canal somewhat long and slightly recurved.

Long Bay, rare, Rev. H. D. Atkinson, a more globose form than any except T. Itanleyi, Angas, of which it is about onehalf the size, and in no way scabrous, the ribs being very indistinet.
Fusus spiceri, n.s., F.t. elongata, turrita, solida, rufo-castanca rel lutea, striis levibus transversilibus (altemantibus parvis et maj.) et costulis undulatis longitudinaliter obsolete plicata; spira (secpé contorta) superné sensim attenuata; apice mamilata vel decollata; anfr. in medio rotundutis; apertura orata, canali longinsculo, recto, terminato; labro simpliei tenui; labio inconspicuo ad suturam tenuiter canaliculato, columella encarsta. Long. 25. Lat. 9. Anf. 8.
F. shell elongate, turretted, solid, reddish chestnut or yellow, cancellate, with smooth transverse striæ (large and small alternating), and undulating longitudinal lines ; obsoletely plicate, lengthwise ; spire (which is often contorted), gradually attenuated abore ; apex mamillate or decollate, whorls rounded in the middle; aperture ovate, terminated by a somewhat long straight canal ; outer lip, simple, thin ; inner lip inconspicuous, slightly chamnelled at the suture; columella enamelled.

King's Island, somewhat common. W. Legrand.
Fusus legrandi, n.s. F.t. subelongata, fusiformi, fuluo-fusca, solidiuscula ; anfractibus 7 , subdeclivis, longitudinaliter plicato-costatis, in ultimo anfi: obsoletis; spiraliter liratis; liris allis, rotundatis, maj. et min. aliquando (speciatim ult. anfrac.) alternantibus, superné obsolete muricatis ; interstitiis epidermidé, subsquamosis, tenuissimeque clathratis; sutura constrieta; apertura pyriformi-oblonga; columella plano-concara ; labro tenni, intus lirato. Long. 38. Lat. 15. Apert. et can. 23.
F. shell subelongately fusiform, brownish yellow, somewhat solid; whorls 7, a little sloping, with longitudinal plicate ribs, which are obsolete in the last whorl ; spirally lirate with white elevated rounded liræ, which sometimes, especially in the last whorl, are large and small alternately and obsoletely muricate above; latticed in the interstices with a somewhat scaly, very thin epidermis ; suture constricted, aperture pyriformly oblong; columella flatly concave; outer lip thin and lirate within.

Rare, East Coast. Mr. Legrand tells me that this species seldom exceeds the dimensions given. It is very different
from F. Tasmaniensis, Ad. and Ang. which is pyriform. Its nearest representative is Fr muricatus Montague (in Testacea Britannica as ALurex m.), lut in that species the costæ are much more distinct.

Siphonalia clarkei. S. testa parva, turrita, subfusiformi, livida ; maculis rufo-fuscis sub peripheriam ornata ; anfractibus (6), declivis, superné angulatis, regione suturali concava; costis radiantibus, (in ult. anfr. 12) obtusis, rotundatis, infra obsoletis, interstitiis concavis costis paulo superantibus ; lirulis spiralibus superné et supra costas obsoletis; canali brevi, vix curvato; apertura ovata; labro intus dentato; labio inconspicuo. Long. 27. Lat. 9.
S. shell small, turretted, sub fusiform, livid (or brown-it varies in color much as Columbella semiconvexa) with reddish brown spots under the periphery; whorls sloping, angulate above, and concave at the suture; radiately ribbed (ribs 12 in last whorl) ribs obtuse, rounded, obsolete below, and narrower than the interstices, spirally lirate ; liræ obsolete above and on the ribs; canal short sloping, but scarcely curved; aperture ovate; labrum toothed within; lip inconspicuous.

From the very full and concise descriptions of Siphonatia fuscozonata, by Mr. Angas "Zool, Proc. 1865," p. 56, our only Australian species, I am able to pronounce this species distinct and new. It is much larger, the ribs more numerous, the color livid instead of white, and the liræ obsolete or absent, and lip toothed within. The brown spots are often deeply shaded at the summit of the ribs, and form a kind of fascia on the upper whorls. The labrum is often thickened into a kind of varix. At Long Bay, D'Entrecasteaux Channel, Legrand and Atkinson.

I have dedicated this interesting species to my dear friend and fellow labourer, the Rev. W. B. Clarke, F.G.S., \&c, so long and eminently connected with the history of Australian geology.

Siphonalia turrita, n.s. S.t. fusiformi-elongata, castanea. rel livida; superne maculis rufo-fulcis zonata, posticé lineis subtillissimis punctatis rufo-castaneis cincta; spira clata, costata ; anfractibus 7, convexis ; ultimo obsoleté nodoso-costato ; apertura orata, intus maculata et fasciata, fasciis interuptis; labro acuto; labio concavo; canali obliqué elongato. Long. 16. Lat. 7.
S. shell fusiformly elongate, chestnut or livid, zoned above with reddish brown spots, and posteriorly girdled with very fine lines of reddish chestnut points; spire elevated, ribbed; whorls 7, convex, last obsoletely nodosely ribbed; aperture ovate, spotted and banded with interrupted color within; outer lip acute ; inner lip concave ; canal obliquely elongated.

Long Bay, rare, Coll. Legrand. A shell very closely resembling S. clarkei, but more fusiform with a longer canal, and
the last whorl vearly smooth, as the ribs are almost obsolete. Thespire is also much turretted, and the outer lip thin and not dentate. The lines of minute dots are also peculiar. Inside the uper zone of spots appears as a serics of longitadinal lines of a aut brown color.

Cominella tasminica, n.s. C.t. ovato-acuta, solidiuscula, in apicé acnta, allo, interlum rirescenti et obscuré fasciata, spirie costutu et mamillata; anfractions $\mathcal{E}$, convexis, superné subcanaliculatis, lirisque eleratis cinctis, strisis longitudimalibus sultilioribus cancellatis; apertura acuté oraté ; laboo simplici ternis, crpenso, obsolcté lirato; labio encunsto, cunali paulluhum curvato. Long. 30. Lat. 17. Long apert. 15. Lat. 8.
C. shell ovately acute, somerrhat solid, with acute apex, white, sometimes greenish and obscurely fasciate; spire costate and mamillate; whorls 8, convex, subcanaliculate above, encircled with liræ and cancellated with very fine longitudinal striæ; aperture acutely ovate; outer lip simple, thin obsolete, lirate, inner lip cnamelled; canal slightly curved, Long Bay. Not uncommon. Rev. H. D. Atkinson, W. Legrand. This characteristic Cominella is distinguished from $C$. costatum by being double the size ; its distinct raised liræ, the absence of any costro on the last whorl and the color.

Cerithiopsis atkinsoni, var. A very distinct variety of Mr. Angas's C. crocea (P.Z.S. 1871 p. 16). It is larger and narrow, of sordid yellow color, instead of orange, and the ribs are not equal, the lower being small. It has however, the fine longitudinal striæ between the ribs. Dredged by the Rev. H. D. Atkinson in Long Bay, 10 fathoms sand.

Conus tasmanicus. n.s. C.t. paria, sulpyriformi-turbinata, coronata, tenui, sub-inflata, lexi, nitente, antice striis distantibus ralidis cincta ; castanca, tribus lineis fulvo alboque maculatis oblique zonata; ad suturas conspicue albo-fulvo maculata; anfractibus 6 , transtersim rugosé striatis, labro tcmui.
C. shell small, subpyriformly turbinate, coronate, thin, subinflated, smooth, shining, with anterior valid distant striæ; chestnut, zoned with three white and fulvous spotted lines; conspicuously spotted with white and fulvous at the sutures, whorls 6 , transversely rugosely striate, outer lip thin.

Very rare. Coll. W. Legrand. Quite distinet from any other Australian form by its color and small coronate habit.
Mitra tasmaica. n.s. M.t. orata, utrimque attemuata, badia, lineis lutco-albis li-tri-fasciata ; spira subelevata, acuminata ; anfractibus 7, plamulatis; longitudinaliter crebré costata, costis parvis, subobsoletis; liris transsersalibus subtillissime cinctis; apertura angiesta; columella quadriplicata. Long. 13. Lat. 5. Long aperture $6 \frac{1}{2}$.
M. shell ovate, attenuate at both ends, brown, with two or
three yellowish white transverse bands; spire subelerate, acuminate; whorls 7 , flattened, thickly ribbed lengthwise with small obsolete ribs, and very finely girdled with transverse lire ; aperture narrowed ; columella quadriplicate.

Rare, Coll. Legrand. The fine ribs are most prominent on the upper whorls. There is a shell very closely allied to this which I have marked as variety $a$, where the ribs are larger and continuous, and another variety where they are smooth, and the whorls coronate.

Mitra scalariformis. n.s. M.t. parva fusiformi-turrita, pallide, lutea, linea albida indistincte zonata; spira acuta; anfractibus 7, rotundatis, eleganter crebré costatis, costis validis, cqqualibus, rotundatis loevibus, nitentibus, antice in ult. anfr. evanescentibus; apertura latiuscula; labro tenui acuto; columella triplicata. Long. 10. Lat. 4. Long aper. $4 \frac{1}{2}$.
M. shell small, fusiformly turretted, pale yellow, zoned .with an indistinct white line ; spire acute ; whorls 7, rounded, elegantly thickly ribbed with valid equal smooth shining ribs, which disappear on the last whorl. Aperture rather wide, outer lip thin, acute, columella triplicate.

Long Bay, rather rare, Rev. H. D. Atkinson. A very pretty shell, the ribsand somewhat turretted spire give it a scalariform aspect. It is somewhat dull in color.
Mitra legrandi. n.s. M.t.minuta, spira sub-turrita, tumida, translucente, nitente, rufo-fulva, alba et linea fulva tenui zonata; anfractibus 5, costatis, costis validis, rotundatis, nitentibus, apertura ovali, columella triplicata. Long. 5. Lat. $2 \frac{1}{2}$. Long apert. $2 \frac{1}{2}$.
M. shell minute, spire sub-turretted, tumid, translucent, shining, reddish fulvous white, zoned with a slender fulvous line; whorls 7, ribbed with valid shining rounded ribs; aperture oval, columella triplicate.

King's Island, rare. A very small shell, varying somewhat in the shades of its coloring, and not unlike III. tasmanica, above described, except that its ribs are more permanent and larger in proportion to its size.
Mitra teresie. n.s. M.t. parva oblongo-ovata, temuiscula, nitente, subventricosa, badia, albida bifasciata; spira breviuscula, vix acuta; anfractibus 5, leevibus tumidis, conspicué nitentibus, ad suturam tenuissimé canaliculatis; apertura orata, intus bifasciata, columella triplicata. Long. 7. Lat. $3 \frac{1}{2}$. Long apert. $3 \frac{1}{2}$.
M. shell small, oblong ovate, somewhat thin, shiny, subventricose, brown, with two whitish bands; spire somewhat short, scarcely acute, whorls 5 , smooth, tumid, shining conspicuously, finely canaliculate at the suture, aperture ovate, bifasciate within, columella triplicate.

Rare, King's Island. A shining banded shell of the series of our II. pica, but much smaller. The coloring seems very
persistent，and，therefore，the species not easily mistaken．I confess，however，that if this species could lose the white bands， and were to have the mouth lirate within，I should regard it as a varicty of MI．scita．I think the lire are not persistent in the latter，and，therefore，the shell may be the same．
Mitra scita．n．s．M．t．parva，ovata，nitente，mulique intense badia，spira obfusé rotundata，atice mamillato；anfractibus 6 ， lavibus tumidis，sutura tenniter impressa ；apertura latiuscula，intus badia，lirata；columolla triplicatce．Long．8．Lat．3⿺⿸⿻一丿又丶刂土 ．Long apert． $4 \frac{1}{2}$ ．

M．shell small，ovate，shining，entirely pure deep brown； spire obtusely rounded，apex mamillated，whorls 6 ，smooth， tumid，suture finely impressed；aperture rather wide，brown within，lirate，columella triplicate．
King＇s Island，somewhat common．Coll．Legrand．Speci－ mens which had been mixed with $M$ ．teresioc．Very distinct from its size，and intense uniform coloring，though belonging to the series of which $M I$ ．badia is a large representative．
Mangelia atkinsoay．n．s．M．t．parve，ovata－fusifomi，tumidi－ uscule，alba，nitìla，epidermidé ferruginea inuluta，linsis obtusé annulatis zonata；spira mamillata；anfractibus 6 ，costutis，costis ralidis（ult．anfr．6）rotundatis；apertura orata，supemé acuta； labro acuto，labio simplici，replicato．Long．3．Lat．$\frac{2}{3}$ mill．

M．shell small，ovately fusiform，somewhat tumid，white， shining，clothed with a ferruginous epidermis；zoned with obtusely angular lines，spire mamillate， 6 whorls，ribbed，ribs valid，rounded（in the last whorl 6），aperture ovate，acute abore；outer lip acute；lip simple replicate．

Rare，East Coast．Coll．Legrand．The minute angular zone on this shell is not easily seen even under the micro－ scope，because of the ferruginous epidermis．This shell has boen dedicated to the Rev．H．D．Atkinson，whose dredging operations have done so much to develop the knowledge of Tasmanian conchology．
Clathurella philonena．n．s．C．t．elonguto－fusiformi，turrita， para，nitente，alba，cul suturam pallidissime fulva fasciata；apice ucuta，fulč ；anfraetibus ř，declivis，superné ungulatis，covexiusculis， longitulinaliter plicutis；plicis costiformibus，rotundutis，regularibus cul suturus arouatis，transcersim liratis ；liris supra plic．transeuntibus， distantibns；apertura ovali；labro incrassato，postice profunde sinuato；labio reflexo phus minuse fulteo tincto．Long．11．Lat． $3 \frac{1}{2}$

C．shell elongately fusiform，turretted，small，shining，white， very palely white banded at the suture；apex acute，fulvous； whorls 7，sloping，angular above，somewhat convex，plicate， lengthrise，with rib like plaits，which are rounded regularly and bent at the suture；transversely lirate，liræ passing over the plaits ；aperture oval；outer lip thickened and deeply
sinuate posteriorly; inner lip thickened, more or less tinged fulvous brown.

A small, almost cylindrically turretted form, with the apex and base tinged brown, and banded. The well defined ribs give it a pretty sculptured appearance. Rather common. East Coast.

Mangella mmaculata. a.s. M. t. fusiformi-turrita, alba, nitente, spira acuta ; anfractibus 9, declivis, ad suturas canaliculatis ad angulum obsoleté tuberculatis, transtersim obsoleté liratis; apertura ovali; labro tenui, sinu conspicuo ; labio simplici, superné tuberculato. Long. 17. Lat. 6.
M. shell fusiformly turretted, white, shining ; spire acute, whorls 9, sloping ; canaliculate at the sutures, angulate and obsoletely tuberculate above, transversely obsoletely lirate, aperture oval; outer lip thin; sinus conspicuous, lip simple, tuberculate above.

King's Island, rare. A white, somewhat elegant species ${ }_{r}$ with a true Pleurotoma spire.

Mavgelia meredithere n.s. M. t. turrita, fusiformi, gracili, spira quam apertura longiore ; nitente, diaphana, alba, fasciis pallide castanea creberimé cincta; anfractibus 6, declivis, superné angulatis et concavis,longitudiualter plicatis plicis opacis, nitentibus, distantibus, curvatis, ad suturam anyulatis; interstitiis subtillissime striatis; striis retate evanescentibus; apertura angusto ovali; labio simplici; labro extus sub-varicoso, intus loevi; margine acuto. Long. 13. Lat. 5.
M. shell turrettedly fusiform, graceful, spire longer than the aperture, shining diaphanous white, very thickly girdled with pale chestnut bands; whorls 6, sloping, angulate and concave above, plicate lengthwise with opaque, shining, distant curved plaits, which are angulate at the suture ; interstices very finely striate, striæ disappearing with age; aperture narrowly oval ; lip simple, outer lip subvaricose outside, smooth within, margin acute.

Bass's Straits, moderately common. A very pretty porcellaneous shining shell, with the ribs distinct, and opaque white. It varies much in coloring, sometimes the chestnut bands are numerous, and of various shades and thickness, at others confined to a simple fascia at the sutures, or the shell is quite white and shining.
Drillia atkinsoni. n.s. D.t. accuminato-turita, fusca, spira acrta, apice mamillato; anfrac. 9, superné angulatis convexis, declivibus, long. costatis, costis parvis, distantibus, subacutis, ult. anfrac. 16, supra angulum et ad suturam validis et transversim tenuiter valide liratis, liris magnis et parvis alterantibus, elevatis, supra cost. transeuntibus et ibi subnodosis; apertura alba, late ovata; labro tenui, expanso, incurvo incrassato, intus levi, postice profundésinuato ; labio planato, levi. Long. 13. Lat. 5.
D. shell acuminately turretted, dusky, spire acute, apex
mamillato, whorls 9 , augled above, conves, sloping, ribbed lengthwise with small distant subacute ribs (in the last whorl 16), which persist over the angle to the suture, transversely finely validly lirate, with small raised lire, alternately largo and small, which pass orer the ribs, and there become subnodose; aperture white, broadly orate; outer lip thin, expanded, incurved, thickened, smooth within, deeply sinuate behind, lip flattencd, smooth.

Rare, Long Bar, dredged from a sandy bottom at 10 fathoms, Rev. H. D. Atlinson. A very pretty shell, finely sculptured, usually very well preserved.

Turritella granulifera. n.s. T. t. acuminato-turrita, crassiusculu, lutea superné et infrıt filleo fuseiatu; anfractibus 12, confertim longitudinuliter striutis, striis undulosis; transversim unicurnatis, carina gramulosi, et obsolete, infra et supra costatis; apertura subquadratu ; lubro in medio simuato. Long. 25. Lat. 8.
T. shell acuminately turretted, somewhat thick; yellowish, with brown bands above and below, whorls 12, thickly lougitudinally striate, with undulating striæ; trausversely ono keeled; keel granulose and obsoletely ribbed above and below, aperture subquadrate; onter lip simate in the middle.

A rery distinct species, with a granular keel, which is of rare occurrence in the genus. Port Arthur, somewhat common.

Turritella acuta. T. t. acutissime laneeolato-turrita, alba, ad basim acuta angulata et concara; anfractibus 15, planulatis, liratis; et longit. unduloso striatis; striis, sub-lamellosis; apertura oblique orata. Long. 30. Lat. 6.
T. shell very acutely lanceolately turretted, white, acutely angulate and concare at the base, whorls 15 , flattened, 7 lirate and longitudinally undulately striate, with lamellar and very minutely dentate strix; aperture oblique, ovate.

Long Bay, rare. Rev. H. D. Atkinson.

[^0]T. scalarina, T. Yorkensis, and T. Brazieri, the last three of Dr. James Cox. These are all Australian, and, as I believe, varieties of one species. I, however, mark the Tasmanian variety as above for future investigators.

Tenagodus weldif. n.s. T. t. volubilis laxa, temuis, alba, diaphana, nitidula, levigata infime flavescente; anfractihus circ. 6 , obliquésulutillissime striatis; rima in anfractilus tribus primis clausis, deinde apertis, marginibus subnndulatis, acutis ; apertura basi emarginata, marginibus irregularibus, acutis, apice septo hemispherico clauso. Long. 12. Diam. aperturce 2 mil.
T. shell loosely twisted, thin, white diaphanous, somewhat shining, smooth, yellow below; whorls about 6, obliquely finely striate; cleft, closed in the three first whorls, then open with subundulating acute margins, aperture emarginate at the base, margius acute, irregular, apex closed with a hemispherical septum.

East Coast, somewhat common. A thin very small shell, closely rolled together at the apex, and then rapidly unfolding. It differs from the T. Australis, not only in its very much smaller size, but also in the slit being entirely open without any small rounded foramina in the upper part. I have dedicated this interesting species to His Excellency the Governor, F. A. Weld, Esq., C.M.G. It may be a variety of Thylacodes decussatus, Gmel., but that is much larger, and of delicate rose color.
Edlima micans. n.s. E.t. minuta, obtusé-turrita, paulocurvata, translucida, polita, albida, apice mamillato, anfract. 7, superné planatis lcevissimis, penultimo rotundato, ultimo subinflato; apertura pyriformi ; labro tenui producto, labio reflexo. Long. 3. Lat. $1 \frac{1}{2}$ mil.
E. shell minute, obtusely turretted, slightly curved, translucid, polished, whitish, apex mamillated, whorls 7, flattened above, extremely smooth, penultimate rounded,last subinflated; aperture pyriform, outer lip thin,produced ; inner lip reflected.

Long Bay. A unique specimen of a very minute, very highly polished translucid Eulima.

[^1]shining, convex; aperture oval, angulate posteriorly, and anteriorly produced and everted.

King's Island, Bass Straits, common, closely resembling some species from Japan. Large for a Turbonilla.

Turbonilla tasmanica. r.s. T.t., suthelato-turvita, nivea, solidiuscula ; anfraetibus normalibus $\&$, rotundutis, suturis impressis; costis elevatis, votundatis, nitentibus, subconfertis, interstitiis levibus; costis in ult. anfr. desincoutilns ; apertura oruta ; anticé incrassata, 2 anfr. apicalibus inflatis, levibus. Long. 7. Lat. 2.
T. shell subulately turretted, snowy white ; somewhat solid, normal number of whorls 8 , which are rounded, with the suture impressed ; ribs elevated, rounded, shining, somewhat numerous, with the interstices smooth; ribs ceasing in the last whorl, aperture ovate, thickened in front, two apicial whorls inflated and smooth.

King's Island, not numerous. The peculiar inflation of the two apicial whorls makes it doubtful whether the species does not belong to the genus Truncatella, but no truncate specimens were seen by me. The mouth is not entire nor rimate.

Cithara tasmanica. n.s. C.t., fusiformi, utrinqué attemuatu, cburnea, inter livas pallidissime rufo tincta; spira elata quam apertura longiore; anfractibus 7, convecis, postice angulatis et superné excaratis ; eleganter longitudinaliter costatis (in ult. anfra. 12-14), et transversim, regularitce lirutis; costis angulatis levibus nitentibus; liris latis planatis; apertura anguste ovata, labro tenni. Long. 12. Lat. 5.
C. shell fusiform, attenuate at both ends, ivory white, between the lire tinged with very pale red; spire raised and longer than the aperture, whorls 7, convex, angular behind and excavate above, elegantly ribbed lengthwise (12-14 in last whorl), transversely regularly lirate; ribs angular, smooth, shining; liræ broad, flattened, aperture narrowly ovate, outer lip thin.

East Coast, rare. Mr. Justin Browne. A delicate, ivory white shell.
Syrnola bifasciata. n.s. S.t. parva, acuté elongata, temui, nitenti, cornea, pallidé fulva bifasciata, polita, subtranslucida; anfractibus 10, convexiuseulis, longitudinaliter tenuiter striatis, sutura impressa; apice mamillata; apertura pyriformi; labro temui; labio reflexo, plica inconspicua, postica. Long. 7. Lat. 2. o
S. shell, small, acutely elongate, thin, shining, horny, with two pale fulvous bands, polished, sub-translucid; whorls 10 , somewhat convex, finely striate lengthwise ; suture impressed; apex mammillate ; aperture pyriform, outer lip thin ; inner lip reflexed, plait inconspicuous, posterior.

Long Bay, 10 fathoms. Rev. H. D. Atkinson. Legrand Only one specimen seen. Syrnola is a genus erected for banded translucent Odostomia.

Rissoina gertrudis. n.s. R.t. mimuta, turrita, subulata, subpyramidulis,lactea, trunslucenti, temui; anfrac. 8, convexinsculis, creberrime plicatis, plicis parcis, rotundatis subobsoletis; ult. aufrac. basim versus spiraliter subtillissime striato; sutura late marginata; apertura semilunari; labro medio dilatato et incrassato; labio conspicto, flextoso, antice rimuto. Long. $4 \frac{1}{2}$. Lat. $1 \frac{1}{2}$.
P. shell minute, turrettedly subulate, sub-pyramidal, milkywhite, translucent, thin; whorls 8, somewhat convex, very thickly plicate with small rounded subobsolete plaits; last whorl most delicately spirally striate towards the base; suture broadly margined; aperture semilunar ; outer lip dilate in the middle and thickened; inner lip conspicuous, flexuous, rimate anteriorly.

King's Island, rare. I have only seen two specimens of this very minute shell, which is near to $R$. nivea, A. Adams, but smaller, and the sutures marginate.

Rissoina (setia) brazieri. u.s. R.t. minuta, turlinato-conoidea, subumbilicate, alba, laté filvo ruifusciata ; anfractibus 5, rotumbatis, levigatis, altimo ad peripheriam angulato; apertura rotundata, superné angulata; peristoma integra. Operculum corneum 3spir. Long. 3, Lat. 2. Testu aliquando epidermide intense olivaceo induta.
R. shell, minute, turbinately conoid, subumbilicate, white, with one broad fulvous band; whorls 5, rounded, smooth, last angulate at the periphery, aperture rounded, angular above; peristome entire. Operculum horny, 3 spiral. This shell is sometimes clothed with a deep olive epidermis.

Isthmus Bay, Bruni Island, where it is very plentiful, entangled in confervoid growths on the rocks.

Cingulina australis. n.s. C.t. minuta, subulata, turvita, tenui, nitente, diaphaneo-alba, anfractilnts 7, carinis elevatis, rotundatis, spiralibus instructis, interstitiis lovvibus; carinis in ultim. anfrac. 5 , deinde 4,8 , etc. ; sutura profunde impressa; apertura oblonga, integra; labro crassiusculo; basi convexo, liris spiralibus (2) elevatis, rotundatis, ornatu. Long. 2. Lat. $\frac{2}{3}$.
C. shell minute, subulate, turretted, thin, shining, transparently white, whorls 7, furnished with elevated rounded spiral keels, with smooth interstices; keel in the last whorl 5 , theu 4, 3 \&c.; suture deeply impressed; aperture oblong, entire; outer lip somewhat thickened; base convex, ornamented with two spiral rounded elevated liræ.

Badger Island, rare. An extremely minute turretted white shell, with elevated spiral keels, \&c.

Dunkeria fasciata. n.s. D.t. minuta, turrita, utrinque clathrata, translucente, pallidé lutea fasciata ; anfractibus 6, convexis, bicarinatis, liris paucis, elevatis, nitentibus spiralibus, transversalibus pulcherrime cancellatis; labio simplici columella arcuata. Long. 31-4. Lat. 2.
D. shell minute, turretted, latticed all over, translucent and
touched with pale rellow; whorls 6, convex, biearinate and beautifully cancellate, with a few elevated, shining, spiral and transverse lire; outer lip simple, columella arcuate.

Bass Straits, ratber common, but so minute that the shell easily cscapes uotice. I may be wrong in assigning the species to the genus Dunkeria. The lattice pattern is so large, and the transverse and spiral ribs, which form it, are so far equal, that it makes a unique form.
Rtsoa (clegula) marle. R.t. mimuta, orato-conica, sub-turvita, translucente, fimmoso-cornea, lutae obsisure fusciuta, anfructibus 4; rentricosis, leclivibus, levigatis, nitentibus; apertura integru, semilunuri, postice anguluta. Long. $2 \frac{1}{2}$. Lat. $\frac{1}{2}$.
R. shell minute, ovately conical, sub-turretted, translucent, smoky horn, and obscurely banded with yellow; whorls 4, ventricose, sloping, smooth, shining; aperture entire, semilunar, angulate posteriorly.

King's Island, common ; a very minute shiny species.
Dhla tumid. n.s. D.t. mimeta, pyramidato-tumida; albida, an suturas sup. et infra luteo fusciutu; anfrac. G, plemulatis, tumidis, obliqué plicatis; plicis subobsoletis; apertura circuluri, labio refleso. Long. $2 \frac{1}{2}$. Lat. 1.
D. Shell minute, pyramidally tumid, whitish, banded with yellow abore and below the sutures, whorls 6 , tumid, but somewhat flattened, obliquely plicate, plaits almost obsolete, aperture circular; lip reflesed.

Swansea, rare. Coll. Legrand.
Diala tessellata. n.s. D.t. elongata, conica, sub-nitente, alba, ar sutur. fascia filluo maculata cineta ; anfraetibus 6 , busi marginatis, planulatis; ultimo anfrac. angulato; apertura ovali, integra, antice sulb-refleca; labro temii ; labio antice subespanso et reflexo. Long. $6 \frac{1}{2}$. Lat. 4.
D. shell elongately conical, somewhat shining, white and girdled at the sutures with a fulvous spotted band; whorls 6 , margined at the base and flattened; last whorl angulate; aperture oval, entire, sub-reflexed anteriorly; outer lip thin; inner lip anteriorly sub-expanded and reflexed.

Common in shallow places. A pretty white shell, with a graceful narrow band of brown spots at the suture. The mouth is faintly emarginate. There is a white variety of this shell, as well as one marked with three or four lines of long purplish spots.
Diala pesctata. us. D t., elongata, coniea, sordide alba, lineis rufo-punctatis, crebrè cinctis; anfractibus 6 , tumide-planatis, spiraliter sulcatis; ultinno anfraetı ad peripheriam obtusé angnlato; sutura impressa; upertura ovata; labro temui; labio reflexo. Long. $7 \frac{1}{2}$. Lat. 3.
D. shell elongately conical, sordidly white, thickly girdled
with reddish spotted lines; whorls 6 , tumidly flattened, spirally sulcate ; last whorl obtusely angulate at the periphery, suture impressed, aperture ovate, outer lip thin, inner lip reflexed.

D'Entrecasteaux's Channel, very common, but in all the specimens, except a very few, the spiral grooves and punctuate markings were worn away, and the shell smooth and snowy white.
Littorina hisseyiana. n.s. L. testa minutissima, globoso-turbinata, tenui, ventricosa ; spira brevi, obtusa, spiraliter densé striata, albida, strigis olivaceis angulato-undulutis, seepe confluentilus pictu; anfractibus (5.) rotundatis; apertura orbiculari, integra; labro interno subreflexo, acuto; columellu subperforata.
L. shell extremely minute, globosely turbinate, thin, ventricose, spire short, oituse, densely spirally striate, whitish, with angulately undulate olive streaks, which are often confluent; whorls 5, rounded; aperture orbiculate, entire; internal lip sub-reflexed, acute, columella sub-perforate. Dimensions.-These shells are microscopic. They vary somewhat in size, but the largest do not exceed $1 \frac{1}{2}$ millimetres in length. About 50 specimens were found in the stomach of a Mullet, Agenostoma diemenensis, Rich. probably caught in the Derwent. The olive markings vary into lines and deeply shaded spots ; sometimes the shell is uniformly olive, or even blue black.

Natica tasmanica. n.s. N. testa obtecté umbilicata, depressoorbiculari, crassa, spira brevi, parum exserta; anfrac. convexis roturdatis, hevibus vel oblique, densé, minutissimé striatis, apertura semilunari, horizontalis, columella tenuicula, cullositate prominente spirali, sulcata, umbilico angulato-excavato ; ad suturam intus callosam; pallide, fulva vel albida lineis pallide fuscis vel aurantaceis fasciatis; basi alba, intus castanea vel fulva. Long. 13. Lat. 16. Anfr. 4. Aper. Long. 10. Lat. 6.
N. shell, with a somewhat covered umbilicus, depressedly orbicular, thick, with a short but slightly exsert spire; whorls convex, rounded, smooth, or obliquely thickly and most minutely striate, aperture semilunar, horizontal, columella somewhat thin, with a prominent callosity, which is spirally sulcate; umbilicus angularly excavate; with a kind of callosity within the suture at the mouth ; pale fulvous or whitish, banded with brownish or orange lines; base white, chestnut or fulvous within.

This shell resembles $N$. plumbea more than any other, but is seldom more than half its size, and very much paler in color. Color is so persistent in the genus that it may well be considered a mark of specific value. If this not very common species has escaped previous naturalists, which, as far as I can learn, it has certainly done, it can only be from its having been
regarded as a small and pale varicty of $N$. plumbea, under which name, and that of $N$. strangei and $N$. baconi, I have scen it in cabincts. It is, however, entirely distinct in form and color and sellom varies from the dimensions given. Hab. E., S.E. and S. coasts.

Natica nana. n.s. N. t. parva, solidiuscula, obliqué ovata, profundé umbilicata, sorlidé alba, subnitente, tenviter longitud. striata; spira subelevata; anfract. 4, rotundato-compexis sublavibus; apertura semilunari; labro temui; lubio recto crassiuscula. Diam. mag. 7. Min. 5.
N. shell small, somewhat solid, obkiquely ovate, deeply umbilicate, sordidly white, somewhat shining, slenderly striate lengthwise, spire subelevate ; whorls 4, roundly convex, smoothish, aporture semilunar; outer lip thin; inner lip straight, somewhat thickened.

Long Bay, about 6 fathoms, in sand, Rev. H. D. Atkinson and Legrand. A small shell, white, slightly shining shell, very different in size and coloring from any other Australian form.

Ruma Globosa. n.s. R. t. profundé umbilicata, obliqué globoso-ovata, alba, epidermide lutea; spira pellucida, convexa; anfractilus 4, declivirentricosis, striis undulatis, subtillissimis, transversè cinctis; apertura elongato-pyriformi; labro simplici; labio postice reflexo nitente. Diam. maj. 27, diam. min. 19.
R. shell deeply umbilieate, obliquely globosely ovate, white, with a yellow epidermis; spire pellucid, convex; whorls 4, slopingly ventricose, transversely girdled with very fine undulating striæ; aperture elongately pyriform, outer lip simple ; inner lip posteriorly reflexed, shining.

East Coast, commou. This large and very elegant Ruma is of a globose habit, of dull white color, but sometimes completely covered with a shining, fibrous, thin yellow epidermis, with much the appearance of having been deposited by the mantle. In spite of its being common, it does not appear to have been described.
Fossarina sinisoni, n.s. F. t. obliqué depresso-globosa, obtecté umbilicata, tenuis, alba sulnitenté, fulvo undulosé maculata, spira planoconvexa, vix elevata; anfractibus 4, tenuissime creberriméque longitudinaliter striatis; ultimo anfracto valdé expanso: apertura rotundata; labro simplici; labio arcuato, postice-dilatato, sulco transverso. Diam. maj.' $6 \frac{1}{2}$. min., 5.
F. shell obliquely depressedly globose, umbilicus somewhat covered, thin, white, somewhat shining, undulately fulvous spotted; spire plano-convex, searcely elevated; whorls 4, very finely and closely striate lengthwise; last whorl very much expanded, aperture rounded; outer lip simple; inner lip arcuate dilated posteriorly, with a transverse groove.

Rare, Long Bay, Bruni Island, Rev. H. D. Atkinson and Legrand. A pretty undulately variegated shell, with the
inner lip produced posteriorly into a kind of channelled triangular elevation. I have dedicated this species to Mr. Augustus Simson, of Tasmania, late of Port Denisor, Qucens. land, an indefatigable collector and investigator into every department of Natural History.

Nassa tasmanica. n.s. N.t. acuminato-ovata, solidiuscula, nitida castanea, luteo-castanea, vel fulva; spira sub-acuta; granoso-plicata (in ult. anfr. plic. 17), plicis superné divisis, anfractilus 5, convesis, striatie, striis sub-distantibus, in ult. anfr. 11; apertura ovata, nitula, all,a; labro solido, superne sub-calloso, intus dentato (dente conspicua in medig); columella valde callosa, callositate alba subrecurva. Long. 12. Lat. 7.
N. shell acuminately ovate, somewhat solid, shining chestnut, yellowish chestnut or brown, spire sub acute ; granosely plicate (plaits 17 in last whorl), plaits divided above by a channel; whorls 5, convex, striate ; striæ sub-distant; 11 iu last whorl; aperture ovate, shiuing, white ; outer lip solid, subcallous above; toothed within, a conspicuous tooth in the middle, columella very callous, with a white subrecurved callosity.

This species is smaller than $N$. fasciata and $N$. pauperata, which it closely resembles in every respect except size, color, and the white callosities at the mouth. It is a pretty conspicuous shell, found ouly on the North and East Coast, where it is rather common. In N. fasciata the plicæ are very distinctly granulate throughout. In N. pauperata they are sub-obsolete except above, and in the present species they are scarcely distinct, except the one which is separated by a groove at the suture. On the whole it is nearer to $N$. pauperata than to $N$.fasc. A shell very like it, oocurs in Port Jackson-N. jacksoniana, as far as size is concerned, but it is white or banded, and has no callosity. The normal color of our species is uniform chestnut, but ali Nassæ vary very much in color. As all the specimens of $N$. jacksoniana seen by me were poor, and thin somewhat stunted shells, it has occurred to me that they were dwarfed specimens of our species, growing in unfavourable circumstances, and that Tasmania is its true bome. In that case the species would be identical, but future observations must decide this.

Cancelleria tasmanica. n.s. C. t. oblonga, alba, spiraliter tenuiter lirata, liris parvis, validis, aqualibus; anfractibus 6 , rotundatis, declivibus; spira acuta; sutura valida; labro tenui, conspicué lirato; columella abbreviato, triplicato. Long. $18 \frac{1}{2}$. Lat. 10.
C. shell oblong, white, slenderly spirally lirate, with small valid equal liræ; suture valid; outer lip thin, conspicuously lirate, columella abbreviate, triplicate.

King's Island, a white finely grooved shell, more elongate than C. leverigata, and nearer in form and babit to Gould's
C. vividula (Sowerby's Thesaurus, vol 11, p. 449, pl. 96, fig. 102) than any other form.

Chesse. libilit.s. u.s. C. t. parva, globosoturbinata, anguste umbilicatu, solilluscula, alba, subopaca, spira clevata, sutura distincter ; anfinct. is, rotundatis, undique temuissime clongaliter transversim liratis, subtillisime long. strintis; ; umbilico callo rotandato marginato; apertura wrutu, antire et postice angulate et conaliculata; labro sub-reflexo, extus fimhriuto rericoso. Long. 4. Lat. 2.
C. shell small, globosely turbinate, narrowly umbilicate, somewhat solid, white, subopaque, spire elevated, suture distinet; whorls 5, rounded, everywhere most slenderly, elegantly, lirate trausversely, and very minutely striate lengthwise; umbilicus margined with a rounded callus; aperture ovate, anteriorly and posteriorly angulate and channelled; outer lip sub-reflexed, and with a fringe-like varix outside.

Loug Bay, 10 fathoms, sand. The fourth species of a very rare genus. The only other are two dredged from Gote's Island in Japan, by Mr. Arthur Adams, and the third from Port Jackson, near the Sow and Pigs, at from 2 to 4 fathoms. This species is distinguished from the others by its reflected and fimbriate lip. The great peculiarity of this genus, says Mr. Adams (who erected it), consists in the canaliculate angular projection at the fore part of the aperture. In this species it is postrriorly channelled as well. C. miranda Ad. is varicose. C. bellulus Ad. has the outer lip thin. C. concinna Angas is pellucid and has the upper whorls punctate.

> Couvmbella banda. n.s. C. t. parva, acuminata, oblonga, intus extusque saturata balia; inconspicuè allidemaculata, spira, acuta, an fractibus $\tilde{\gamma}$, planatis, levibus nitentibus; apertura breviuscula; labro intus dentato; coturnelli obscuré corrugata. Long. 9. Lat. $3 \frac{1}{2}$.
C. shell small, acuminately oblong, saturated brown without and within, inconspicuously white spotted, spire acute; whorls 7, flattened, smooth, shining; aperture somewhat short, outer lip toothed within, columella obscurely corrugate.

Smansea, East Coast, common. A uniformly purple brown shell, faintly variegated when worn. There is an orange red variety from Brown's River and Blackman's Bay, which may be a different species.

Columbella roblint. u.s. C. t. parra, aciculari-ovata, sub-nitente, pallide castunra, undique crebré cllo-futio maculata; anfractilus 7 , pulemulatis, a pice mamillato, intensé fusco; aperturu latiuscula, labro obsolete dentato; columella corrugata. Long. 9. Lat. 4.

Var. a. Sanguineo-fulco maculeta.
C. shell small, acicularly ovate, somewhat shining, pale chestnut, everywhere thickly spotted white and fulvous ; whorls 7 , flattened, apex mamillate, of a deep smoky brown; aperture somewhat broad, obsolutely toothed. Var. a. sanguineously brown spotted.

Common on the East Coast, Storm Bay, etc. It may be only a variety of C.badia, which it resembles in shape and size, but the markings seem only to vary within certain limits; becoming sometimes an interrupted band of blood red spots.
Columbella lecrandi. n.s. C. $t$. parva, subulata, temui, nitente, castanea, maculis niveis fulvo umbratis ad suturas cingulata; a pice mamillato ; anfiactibus, 6, elongatis, convexis, trunsversim subtillissime lineatis; apertura elongata ovata; labro tenui, simplici. Long. $7 \frac{1}{2}$. Lat. 2.
C. shell small, subulate, thin, shiny chestnut, girdled at the suture with a band of snowy spots, shaded with fulvous brown; apex mamillate ; whorls 6 , elongate, convex, very finely transversely lined; aperture elongately ovate; outer lip, thin, simple.

King's Island, very rare. T'wo specimens only submitted to me, but both well preserved. A small mamillated subulate form, which cannot be mistaken for any other.

Columbella minuta. n.s. C. $t$. ovata minuta, leevi, nitente, pallide castanea longitudinaliter crebré lineis castaneis ornata, et maculis albis transversim bifasciata; anfractibus 5, planulato tumidis; apertura ovata, postice acuta, labro incrassato, intus dentato. Long. 3. Lat. $\mathrm{I}_{\frac{1}{2}}$.
C. shell ovate, minute, smooth, shiny, pale chestnut, very thickly ornamented with chestnut longitudinal lines, bifasciate transversely with white spots; whorls 5, somewhat flatly tumid, aperture ovate, acute posteriorly, outer lip thicizened, dentate within.

Swansea, East Coast, common. One of the smallest Columbellas known, and like all its congeners variable in color, but in the unworn specimens, the above characters seem pretty constant.
Euchelus tasmanicus. n.s. E. t. parva depresso-turbinata, carneo alba, punctis rufis aliquando in lineis obliquis maculata; anfractibus 4, declivi-rotundatis, livis granulosis creberrimé gemmatis, interstitiis longitudinaliter plicatis, ad suturas canaliculato impressis; apertura obliqué ovata, subcirculari ; labro intus lirato; labio post columellam bisulcato, et obliqué striato. Diam. maj. 6, min. 5.
E. shell small, depressedly turbinate, fleshy white, spotted with red points, which are sometimes disposed in oblique lines; whorls 4, slopingly rounded, thickly gemmed with granulous liræ, the interstices plaited lengthwise, with a channelled impression at the sutures; aperture obliquely ovate, subcircular, outer lip lirate within, inner lip bisulcate and obliquely sulcate behind the columella.

Long Bay, Bruni Island, and S. Coast. This somewhat gibbous Euchelus appears to have traces of nacreous iridescence, internally. It is very distinct in size (being the smallest of our species) from E. baccatus, MIke, though somewhat near shape and color. Rather scarce.

Gibrula aurea. n.s. G. t. parva, turbinato-conoidea, vix, umbilicata, luteo alba, maculis rufo-aureis, pulcherrime picta; anfractibus 4, p,asim marginatis et planulatis, superné rotundatis, ad suturam constrictis; liris irregularibus, oblique subtillissime striatis cinctis; marginé eleganter alba et rufo-aurea tessclato; basi convexiusculo, lineis concentricis impressis tesselatis sculpta, apertura rotundata. Long. alt. 5, diam. 4.
G. shell suall, turbinately conical, scarcely umbilicate, yellowish white, painted very prettily with reddish gold spots; whorls 4, margined at the base and flattened, rounded above and constricted at the suture; girdled with irregular obliquely striate, very fine striæ; margin elegantly tesselated, with white and reddish gold; base sculptured with impressed tessellated lines. Aperture rounded.

King's Island, rare. A very pretty shell, which is very nacreous underneath.
Cantiaridea ornata. n.s. C. t. vix umbilicata, conoideo-turbinata fusso et viridi variegata; anfractibus declivi planulatis, supernè conspicué tuberculatis (in ultimo anfractu decem), obsolete oblique corrugatis et subtillissime decussatis; ultimo anfractu al peripheriam acute angulato et obtuse tuberculato; basi planato, decussatim granato liris tribus fusco maculatis ornato; apertura subquadrata, columella arcuata et canaliculata ; labio acuto. Long. 19. Lat. 20.
C. shell scarcely umbilicate, turbinately conoid, variegated brown and green; whorls sloping and flattened, conspicuously tubercled above (tubercies in the last whorl 10 in number), faintly obliquely corrugated and very finely decussate; last whorl sharply angulate, and obtusely tuberculate at the periphery ; base flattened ; decussately granular, ornamented with three brown spotted liræ ; aperture subquadrate, columella arcuate and canaliculate; lip acute. Seen from above the tubercles seem radiate, like the spokes of a wheel.

This shell, with some others, were given to me by Mr. Ronald Gunn, the eminent botanist and naturalist, to whom Tasmania owes so much. He found it seldom, and on the north cost only. It is a very beautiful species with bright emerald green markings, and shelly operculum. It is closely called to C. aureus, Jonas, but distinguished by its color, larger size, and the yery conspicuous tubercles crowning the whorls.
Liotia tasmantca. n.s. L. t. parva, discoitea; sordide alba, spira plano-depressa, costis spiralibus subobsoletis, ct liris longitudinalibus creberrimé ornata; peripheria carinis duobus nodosis, nodis in 2 anfr. elevatis et imbricatis ; apertura margine reflexo incrassata ; umbilico peramplo, spiraliter dentato. Diam. maj. 8, min. 6. Alt. 3.
L. shell small, discoid, sordidly white, spire plano-depressed. ornamented thiekly with spiral sub-obsolete ribs and longitudinal lire, with two nodose keels at the periphery, nodæ in the second whorl raised and imbricated, aperture with the
margin reflexed and thickened, unbilicus very wide and spirally dentatc.

Long Bay, rare. Rev. H. D. Atkinson. This shell is nacreous within, and very near in form to $I$. discoidea Reeve. The nodæ on the upper carina become little raised hollow rounded squamæ on the second whorl.

Monilea rosea. n.s. Mr. t. minuta, turbinata, late umbilicata, rosea, maculis albis variegata: anfractibut 4, rotundatis, striis albis magnis et parvis alternantilus cinctis; apertura integra, rotundata; labro proclucto ; lalio simplici ; margine umbilici callo inconspicuo, albo, corrugato instructo. Diam. 3.
M. shell minute, turbinate, widely umbilicate, rose color, variegated with white spots, whorls 4 , rounded, encircled with white alternating large and small striæ; aperture entire, rounded; outcr lip produced; inner lip simple; umbilical margin furnished with a somewhat inconspicuous white corrugated umbilicus.

This small shell is of intense carmine color in some specimens. The outer lip is produced very much from the suture so as to give the aperture a sunken appearance. The callosity at the umbilicus is only perceptable under the lens iu very good specimens.
Gibbula depressa. n.s. G. t. depresso-orbiculata, fulvo-purpurea lugubre tincta; umbilicata, late sulcata, sulcis transversim striatis; anfractibus 5, depressis; ultimo anfracta permagno, cingulis sex subelevatis, transversis, aliquando tessellat is insigno ; apertura obliquè subquadrata, intus lirata, roseei viridique splendidé irridescente, labro tenui ; lalio subreftexo. Diam. 10 mill.
G. shell depressedly orbiculate, lugubriously-painted fulvous brown and purple, umbilicate, widely sulcate, sulci transversely striate; whorls 5, depressed, last whorl, which is much larger, distinguished by 6 transverse sub-elevated, and sometimes tessellated belts ; aperture obliguely sub-quadrate, lirate within, and splendidly iridescent with rose and dark green; outer lip thin; inner lip sub-reflexed.

Adventure Bay, common. This shell is always more or less encrusted with Polyzoa (Membranipora and Cellepora). It might easily be mistaken for young slells of Trochocochlea striolata. Its depressed, almost angular, form and interior iridescense, render it easily recognised.

[^2]impressed lines; aperture sub-quadrate ; outer lip acute, inner lip simple.

Rare, Chappell Island, Bass' Straits. A small conical form, whose nearest congener is our reversed $Z$ incertus Reeve. Its peculiarity for an Australian form of the genus is the absence of granulations on the lire.

Ziziphinus allporti. n.s. Z.t. tumido-conica, solidiuscula, alla: anfractibus 6, cmmexo-decliribus; liris transeresis, granulosis cinctis; granulis rotundatis, interstitios longitudinalibus oblique separutis; sutura canaliculata; ultimo anfractu al peripheriam rotundato ; basi convexiusculo, lineis subpranosis impresso; aperlura obliqué quadrata; labro intus lirato, infra billentato, labio simplici. Alt. 11. Diam. 9.
Z. shell tumidly conical, somewhat solid, white; whorls 7, convexly sloping, girdled with transverse granular liræ; granules rounded, separated by oblique longitudinal strix; suture canaliculate, last whorl rounded at the periphery, base somewhat convex, impressed with sub-granular lines; aperture obliquely quadrate : outer lip lirate within; bidentate below; inner lip simple.

Islands in Bass' Straits, very rare. A white, small, tumid shell, in habit much resembling a Thalotia.

Clanculus aloysir. n.s. C. turlinato-conoidea, umbiticata, albila, lineis et maculis intensé fuscis, vel atratis variegata; anfiactibus 5-7 planulatis, transecrsim sulcatis, el cingulis granosis ornulis (cingul. 5 in ult. anfo.), cingutis superiorilus et inferioribus granulis majoribus conspicuis; sutura subcanaliculata; anfractu ultimo ad peripheriam subcarinato, basi planiusculo cingulis granosis ornato; columella contorta, superné et infradentato dentibus parvis ; lubro lirato et denteto; margine umbilici spiraliter striuto. Diam. 11.
C. shell turbinately conoid, umbilicate, whitish, variegated with lines and spots of deep dusky brown or blackish; whorls 5 to 7, flattened, transversely sulcate and ornamented with granular belts (belts 5 in the last whorl), upper and lower belts conspicuous by their larger granulations; suture subeanaliculate ; last whorl subcarinate at the periphery, base somewhat flattened and ornamented with granular belts; columella twisted, dentate with small teeth above and below, outer lip lirate and dentate, umbilical margin spirally striate.

Though the Clanculæ vary somewhat in coloring, it is always within certain limits. There is no other black and white Clanculus among our Tasmanian species, which are numerous.
Clanculus rmbomene. n.s. C. t. depresso-conicu, alla; anfrac. 5, ad suturas canaliculatis, concavis, marginibus utrinque moniliferis, infra mar!, 3-4 liratis; liris granis circular.niteutib. ornatis, interstitios subtillissime obliqué striatis; ultimo anfract. acute angulato et marginato; basi plreno, spiraliter gramulose lirato; apertura oblique quadrato; labro intus liruto: columella unidentuto et corruguto; margine umbilico spiratiter ilentuto. Diam. mag. 11. Alt. 10.
C. shell depressedly conical, white, whorls 5 , at the suture
canaliculate, concave, with both margins beaded, within the margins 3-4 lirate; liræ ornamented with round shining granules, interstices very finely obliquely striate, last whorl acutely angulate and margined; base flat, spirally granulosely lirate ; aperture obliquely squared; outer lip lirate within; columella unidentate and corrugated; umbilical margin spirally dentate.

One specimen. A very distinct white shell with moniliferous whorls rising in stages.

Cylichna atkinsoni. n.s. C. t. parva, cylindracea, angusta, tenui, ferruginea, spira umbilicata, occulta, tenuissime long. et transversim striata, sordide alba; labro tenui, acuto, medio coarctato, antice subdilatato; labio angusto, reflexo. Long. $4 \frac{1}{2} . ~ L a t .2$.
C. shell small, cylindrical, narrow, thin, ferruginous, spire umbilicate, hidden, very slenderly lengthwise and transversely striate, sordid white, outer lip thin, acute, drawn in at the middle, and sub-dilate anteriorly; inner lip narrow, reflexed.

Long Bay, not common. A very small shell, brought up occasionally by the dredge from 10 fathoms; sandy bottom. Rev. H. D. Atkinson. The other Tasmanian species is $C$. arachis, which is Australian also. In its young state it can always be distinguished from the foregoing by the dense undulating transverse striæ with which it is covered.

Aplysia tasmanica. n.s. A.t. tenui fragili, translucente, nitente, oblique subquadrata, tenuiter concentrice striala, et transversim minute sulcata; intus subtestacea, leviter concava, encausta, cornea; apice vix incurvo ; margine superiori subreflexo, arcuato ; margine inferiori obliquo recto, antice producto, rotundato. Diam. mag. 38, transversim diam. max. 28 mil.
A. shell thin, fragile, translucent, shiny, obliquely subquadrate, slenderly concentrically striate and transversely minutely sulcate, subtestaceous within, slightly concave, enamelled, horny, apex scarcely incurved, with the upper margin arcuate aud subreflexed; lower margin oblique and straight, anteriorly produced and rounded.

A large form of talcous appearance, the margin becoming insensibly membranaceous. It is somewhat similar in form to A. gigantea, of Syduey, but more oval, membranaceous, and smaller.

Achea marmorata. n.s. A. t. quadrato-oblonga, postice dilatata depressa, sordide olivacea, apice croso vel acuto, submediano ; costis 8-10, rudis, erosis, radiantibus, clistantibus; intus nitente conspicue variegata, radiis luteis concavis, interstitiis atrofusciss; spathula nigerrima, margine albo, atro-punctato conspicuo. Long. 21. Lat. 15. Alt. 6.
P. shell quadrately oblong, dilate behind, depressed, sordidly olive ; apex corroded or acute, submedian; ribs 8-11, wide, corroded, radiating and distant; within shiny and conspicuously variegated, with white rays and very black broad
interstices, spathula, black, with a white conspicuous margin.
Common. The intensely black marbled appearance of the interior of this shell will distinguish it at once. It is found, I am told, in New South Wales, but rarely.

Patella tasmanica. n.s. $P$. $t$. orata, solida, sordide luteo-alba, scepe corrosa; apice sulmactiuno; costio radiantibus, 21 circiter, validis, anyulatis; interstitiis liris subtillitus subimbricatis profuse ralliata; intus cburnea, nitente plus minusre lutco tincta, margine angusta, elegantissime pectinuta, intus corruleo tenuissime lineato, extus linca fusca interrupta marginato ; spathala vix definita. Long. 49. Lat. 33. Alt 20.
P. shell ovate, solid, sordidly yellowish white, often corroded, apex sub-median with about 21 valid, angular radiating ribs, and the interstices rayed profusely with very fine subimbricated lire; within ivory white and shiny, more or less tinged with yellow; margin narrow elegantly pectinated; margined with a very fiue blue line within, and an interrupted dusky brown line outside. Spathula scarcely defined.

Recherche Bay and south generally. Nearer to P.alticostata Angas than any other.
Patella chapmani. n.s. P. t. ovata, postice latiuscula, depressa, rufa rel ustulata, el nebuloso brunca; apice acuto, submediano; costis radiantilus $\mathcal{S}_{\text {., plus minusve validis, depresso rotundatis; liris subtillilus }}$ projuse rauliata, et sulcis irregularibus cincta ; margine angulato, noduloso; intus alba et pallide rosea nebulosa; spathula vix visibilis. Long. 20. Lat. 15. Alt. 5.
P. shell ovate, somewhat broad behind, reddish or scorched and nebulously brown, apex acute, submedian, with 8 radiating ribs more or less valid, and depressedly rounded, profusely radiate with very flne liræ, and girdled with irregular sulci; margin angulate, nodulose; white within and clouded pale rose color, spathula scarcely visible.

Very rare. Four of the ribs are posterior, and the four anterior are smaller. I have dedicated this shell to Commodore Chapman, of H.M.S. Dido, an industrious conchologist, and from whom I received valuable assistance in preparing my list of Tasmanian Mollusca.

Macroschisma tasmanica. n.s. M. t. orato-oblonga, dorso clevata, conrexa, pallidé luteo-castanca, radiatim atrata, lincis clecatis, nodulosis, rarliata; sulcis concentricis irregularibus, rugosa, lineis concentricis confertissimis seulpta; extrcmitatibus rotunlatis; postice elcrata. Foramen maynum, clonyatum, subtriangulare, postice dilatatum, excavatum. Long. 32. Lat. 18. Alt. 9.
M. shell ovately oblong, dorsal region raised and convex, pale yellowish chestnut, with blackish rays; radiate with nodulous elevated lines; rough, with irregular concentric sulci, sculptured with very close concentric lines, ends rounded; posterior end raised; foramen large, elongate, sub-triangular, dilate and excavate behind.

The common Macroschisma, of Tasmanian coasts. Until
noiv it has been confounded with $I I$. producta (A. Adams, Pro. Zool. Soc. 1850 1. 202, sp. 7) which is a narrower shell, less distinctly ribbed, and with a narrow and somewhat constricted forameu.

Auricula (Rhodostoma) dyeriana. n.s. A. t. orata, inflata, subumbilicata crassa, rimide allicante, fulro bifasciata, striata, striis reyularibus, distantibus; anfiact. 6, suturis obsoletis; spire conica, planata; apertura integra, nitente, pallille futra; labro incrassato, bilabiato, intus conspicué trianyulari inciso et dentato; labio lidentato; umbilico clauso, marginato. Long. 14. Lat. 9.
A. shell ovate, inflated, subumbilicate, thick, greenish white, with two fulvous bands, striate, striæ regular, distant; whorls 6 suture obsolete; spire conical flattened, aperture entire, shining pale fulvous, outer lip thickened, bilabiate, with a triangular notch within, inner lip bidentate; umbilicus closed and margined.

North Coast, brackish waters. There is a shell somewhat like this described by Mr. Swainson (Proc. Roy. Soc. Tas. Vol. 3, p. 45), from Dr. Milligan's collection, and probably from Australia, but it is large, of different color, and with a semicircular notch on the outer lip. I have named the species after Mr. Dyer, of Hobart Town, the industrious collector, who discovered it at Kelso.

Pecten marle. n,s. P. t. trigonali-orbiculari, subcequiralia, depressa, velce dextra paulo convexiore, auribus incqualibus, rosce cel roseo-rioluscente, nebulis purpureis et lineis maculisque allis peculiariter marmorata; costis 8 irregulariter lony. suleatis, et obsolete squemutis, lirisque pervioribus, intermediis incqualibus radiatis, superficic tota tenuiter squamose imbricata; auribus radiatim costatis, costis nodosé imbricatis ralvis intus violaceis, sericeis. Long. et. Lat. 44. Alt. 16.
P. shell triangularly orbicular, subequivalve, depressed, right valve a little more convex, ears unequal ; rose color or rosy violet, and peculiarly marbled with purple clouds, and white lines and spots; ribs 8 , irregularly sulcate lengthwise and obsoletely scaly ; radiate with smaller lire ; surface wholly finely imbricately squamose; ears radiately ribbed, ribs nodosely imbricated, valves colored a kind of silky violet within.

East Coast and Maria Island. Rather uncommon. Nearest to Sowerby's Pecten serratus. The fine shagreen marking is different from $P$. bifrons, inasmuch as the scales are finely pointed. The violet hue of the inside and silky appearance are very constant. The obsoletely squamose ribs vary, but it is a character not seen iu any other Tasmanian species.

[^3]D. shell suborbicular subinflated, subattenuate towards the umbones, snowy white, somewhat shining, and under the lens elegantly irridesecut, umbones lightly spotted with pink, slenderly striate, and decussate very finely and elegantly with fine strix, ligamental area narrowly lanceolate, lumule small, broadly cordate, impressed and carinate in the middle; pallial sinus deep aud obtusely triangular,

East Coast, uncommon. A very beautifu' snowy white, and neatly rounded shell. The transverse strix are very regular and corbis like.

Calista victorie. n.s. C. t. trigono-subcordutu, crasset, tumida, antice rotunlata, postice oltuse an!!nlatu, incrquelaterali, confcrtissime concentricé striate (striis anticilemellosis, lemellis 3, vel. 4, pervis, cressis) ; subnitida, pallide carnen, lincis latis innqualibus, rufo-cestancis, longitudinaliter puncirarliata; lamule clongatr, tenuistriata, linect impressa circumscripta; latere postico oltusé auguluto, plenato, ruyosé striatu ; ralcis intus, nitertilus, rufolutcu nebulosis, muryiné denticuluto. Long. 55. Lat. 60. Alt. 35.
C. shell triangularly subcordate, thick, tumid, rounded in front and posteriorly obtuse'y anguate, ine quilateral, very thickly concentrically striate (strix anteriorly lamellose with 3 or 4 thick small lamellæ) somewhat shining, pa'e flesh color, rayed lengthıvise, with few broad unequal reddish chestnut lines; lunule elongated, slenderly striate, circumscribed with an impressed line; posterior line obtusely angulate, flattened, and rugosely striate ; valves shining very much within, and c'ouded reddish yellow, margin denticulate.

A somewhat common shell on all the South Australian and Victorian costs, and is said to occur in S. E. Austra ia, but the identification is doubtfu', as it has been cunfounded with $C$. rutila, Sow., with none of the description or figures of which it corresponds. The specimens from which the description is taken came from Cloudy Bay on the South of Bruny Island. It also is found in Frederick Henry Bay. I have never found it except on sandy exposed coasts where there is a heavy surf.

Vererupis reticulata. n.s. V. t. transcersa, subquedrata, tenui, dcprcssa, valde inaquelaterali, untice rotundute, brevi, posticc depressiuscula, latiorc, subtruncata; costis transerersis obsolctis, planatis, divaricatis, undulosis creberrimé cincta (sublentc) ; unliqué tenuissime longitudinaliter striata ; valcis intus albis, cardine parto incequaliter tridentato, dentibus medianis et posticis bifidis ; sinu pallii angusto, rotundato, oltuso. Albida, postice lincis angulatis atro reticulata, aliquando versus umbones radiation rosca tincta. Long. 17. Lat. 17. Alt. 12.
V. shell transverse, subquadrate, thin, depressed, very inequilateral anteriorly rounded, short, somewhat depressed, posteriorly and border very thickly girdled with transverse obsolete flattened, undulating ribs, under the lens longitudinally striate in every part; valves white within, hinge small, unequally trilentate, with the median and posterior tecth
bifid, pallial sinus narrow, rounded, and obtuse. White reticulated posteriorly with black angulate lines, sometimes radiately rose tinted towards the umbones.

Not uncommon on South coast. A small shell, very distinct by its finely crenalately striate obsolete ribs, and reticulate markings.

Myodora tasmanica. n.s. M. testa albida, curvato-ollonga, antiec leviter Aexuosa, alrupte truncata, valva sinistra ventricoso-convexa, dextera distincte concara; eoncentrice striate ; striis paucis, rotundatis latiusculis, subdistantibus, regulariter, crescentilus; sublent clegantissime, tenuissime decussata.
M. shell whitish, curvately oblong, anterior slightly flexuous, abruptly truncate, left valve ventricosely convex; right valve distinctly concave, coneentrically striate with a few round, somewhat broad, sub-distant ridges, which increase regularly towards the margin, and very finely and beautifully decussate with undulating striæ. Long. 17. Lat. 13. Alt. 4.

This very distinct species of Myadora has more affinities with the Australian II. pandoraformis than any other, but it has no movable testaceous appendage, and the valves are both distinctly striately ridged. Hab. Long Bay.

Myodora albida, n.s. M. testa albilda, translucida, subquadrata oblonga, subconvexa, anticé latissimé truncata; concentrice striata; striis elevatis, rotundatis, reyularibus, paucis, prope maryincm antieam angulatis.
M. shell whitish, translucent, subquadrately oblong, subconvex, very broadly truncate auteriorly, concentrically striate, striæ rounded, raised, regular, few, angulated near the anterior margin. Long. 10. Lat. 6. Alt. 2.

A very pretty species, differing from the last in its subquadrate form, and its convex valves, which are both regularly and distinctly striate. Hab. Long Bay.

Anapa tasmantca. n.s. A.t. crassa, trigona, gibbosa, cequiralri, antice rotundata postice angulata ct planata, sordide alba, coneentrice tenué sulcata,versus marginem epidermidé olivacca induta; umbonibus parvis, incurvis obliquis distantibus; area ligamentali parva, inconspicua, aperta; pagina, interna nivea nitente, sinu palli nullo. Long. 19. Lat. 19. Alt. 16.
A. shell thick, trigonal, gibbous, equivalve, rounded anteriorly, angulated posteriorly and flattened, sordidly white concentrically finely sulcate, clothed with an olive epidermis towards the margin; with small incurved distant umbones, ligamental area small, inconspicuous, open, interior surface snowy white and shining, no pallial sinus.

This shell appears to me to have been confounded with $A$. smithii and A. triquetra, which is a synomym of Gray. That shell is not found in Tasmania. It is, however, a much smaller and thinner shell, less tumid and more trigonal, with very much the appearance of a Cyclas. I cannot find that it has been described.

Pinna tasmanica. n.s. $P$. $t$. orato-cunciformi, tenui, subrentricosn, maryinibus rotumlatis, sordile olineca, purpureo mbulose, ruliutim costata, costis interdum obsoletis, subnolosis, versus maryinem sparsim, irregulariter squenosis, squumis derosis subtubuliformis ; upicc subtruncato, lirido. Long. 190. Lat. 85. Alt. 2 S .
P. shell ovately cunciform, thin, subventricose, margins rounded, sordidly olive, clouded with purple, radiately ribbed, ribs sometimes obsolete subnodose, and towards the margin sparsely irregularly scaly, scales elevated subtubuliform, apex subtruncate, livid.

Rare. On the north coast only. W. Legrand. This fine Pinua is one of the very fer of the genus, with the margins rounded and not angulate. In this respect, and in the few irregularly much raised tubular seales, it is quite distinct from $P$. zelania, which is not uncommon in Australia.

Mrtilicardia tasminica. C. t. elonyato orata, in. medio constricta rel sinu profundo distorta, luteola rel sorlide alla, epidermide fusca, maxime incequilaterali, antico brecissima, subtruneata, postice dilatatu, inferne sinuosa et hiante, radiatim costata, umbonibus minimis compressis apmoximatis obliquis; lunula inconspicua, profunda; costis incequalibus, irregndaribus, fexuosis, postice lamellosis et obsoletis, primis in latere antico angustioribus, alteris sensim latioribus. Long. 10. Lat. 21. Alt. 14.
M. shell elongately ovate, narrowed in the middle or distorted, with a profound sinus, yellowish or sordidly white; with a dusky epidermis, very inequilateral, extremely short anteriorly, subtruncate, dilated posteriorly, sinuous and gaping below, radiately ribbed, with small compressed approximate oblique umbones; lunule inconspicuous, very deep, ribs unequal, irregular, flexuous, lamellose and obsolete posteriorly, the first on the anterior side somewhat narrower, the others becoming gradually wider.

Blackman's Bay, uncommon. Distinguished from M. excavata by the epidermis, and the ribs beiug smooth instead of having the lamellar projecting scales.

Mytilus tasmanicus. n.s. M. t. oblongo-orali, tumida, crassa, concentrice tcnué irregulariter striata, cpirdermide atro-purpurea, basim versus sparsim, irregulariter larbata capillis longis, corneis, discisque calcareis radicatis; maryinibus intus extusqus viride viride pceuliariter encaustis; umbonibus terminalibus, parris, acutis, curratis nitentibus, glabratis, parum margarataceis; fossulaulligamentum rccipiendum sutisprofunda ; pagina interna nivca, impessione pallii et musculari tantum iridcscente, ligamento longo conspicuo. Long. 175. Lat. 75. Alt. 45.
MI. shell oblong, oval, tumid, thick, concentrically finely irregularly striate, epidermis black purple, towards the base sparsely and irregularly bearded with long horny hairs, which are rooted in calcareous discs; the margins peculiarly enamelled a vivid green both outside and inside; umbones small acute, curved, shining, smoothed, slightly pearly, fossula for the ligament somewhat deep; internal surface snowy white,
the pallial and muscu'ar impressions alone being iridescent, ligament long, conspicuous.

A truly magnificent species, which is so large that it must almays be a conspicuous object, yet the peculiar and brilliant green enamel of the edges makes it still more so. It is only formd in deep water in Storm Bay. The only shell approaching to it in character is M. latus, of New Zealand.

Prthina tasmanta. n.s. P. t. parea suborbiculari, conrexa, alba, sulcis concentricis et costis bifariam ralliantibus eleganter clathruta; costis angulatis postice curratis parumque elccatis, umbonibus, submclianis obliquiis, parici. Long. 7. Lat. 8. Alt. 3.
P. shell suborbicular, convex, white, elegantly latticed with concentric sulci and ribs radiating in opposite ways; ribs angulate and curved, and slightly raised behind, umbones submedian, oblique and small.

This e'egant Pythina is very distinct from the common $P$. deshoyesi, which is larger, has the divaricating ribs somewhat lamellose behind, and is not latticed with transverse sulcations. King's Island, rare.

Tellina marie. T' t. transtersa ellipitica, subinflata, nitente, lactea, tenui cequilaterali, inrequirnlvi, postice hiante, artice late rotundate, postice rix attenuato, tlexura minima, undique crełré tenuiter sulcata, ligamento pallide castaneo prominulo. Long. 22. Lat. 23.
T. she l transverse, elliptical, subinflated; shining, milk white, thin, equilateral, inequivalve, gaping posterior y , widely rounded in front, scarcely attenuated behind, flexure very slight, thickly and finely sulcate, ligament pale chestnut, somewhat prominent.

Rather uncommon. South Coast. W. Legrand. A white shell, with no determinate characters except its oval form, absence of color, and almost perfect absence of flexure. There are are three small hinge teeth in one valve, and two in the other, and the pallial sinus is very large.

Luciva mintua. n.s. L. t. paria subrentricosa, oblonga transrersa, tenui, alba, tenui-costata, costis numerosis concentrice, tcnuiter, regulariter elegantissimeque striata, valde incequilaterali, latere antico longiore rotundato, postico latiore, maryine integro, umbonibus productis obliquis, parris incurvis, conspicue concentrice striatis; ralris intus allis, impress. mus. conspicuis; ralr. dect. in merl. unidentato dente bifido, val. sinis. bidentato, dente antico bifido. Long. 8. Lat. 9. Alt. 5.
L. she 1 small, subventricose, oblong, transverse, thin, white, slenderly ribbed, ribs numerous, finely regu arly and most e egant'y striate; very inequilateral, anterior side the longer, rounder, the posterior side wide; margin entire, umbones produced, oblique, small, incurved, conspicuously concentrically striate, valves white within, muscular impression conspicuous, right valve unidentate with a bifid tooth; left valve bidentate, the anterior one bifid.

Badger Island, rare.

[^0]:    Trexcatella tasmanica. n.s. T. t. decollata cylindraceo-turrita, parcu, temui, nitente, pallida; anfractibus 5 (non decoll. 7) convexiusculis, plicis parvis sub-acutis,confertissime instructis (in ult. anfrac. SO-35) apertura pyriformis; superné angulata et suleata; labro bimarginato sub-expanso, labio inflexo. Long. 7. Lat. 3.
    T. shell decollate, cylindrically turretted, small, thin, shining, pale fulvous, whorls 5 (if not decollate 7), somewhat convex, furnished very thickly with small subacute plaits (in last whorl 30-35) ; aperture pyriform, angulate and sulcate above; outer lip bi-marginate sub-expanded; lip reflected; peristome continuous.

    Bass Straits, common. The plaits or ribs on the shell are rery like those on most Scalaria. For my own part I think, it very difficult to distiuguish the species from T. teres, $P f$ i.,

[^1]:    Turbonilla marie. T. t. elongata, turrita, tereti, solidiuscula, opaca, lactea; anfractibus 12, vix convexis vel planulatis; costis numerosis, declivibus, crassis, rotundatis, levibus ; interstitiis inconspicuis, parvis,latitud. costis cequantibus; anfractu ultino costis ad peripheriam vix obsoletis; basi lcevi, nitenti, convexo ; apertura ovali, postice angulata antice producto et everso. Long. 10. Lat. 2.
    T. shell elongate, turretted, terete, somewhat solid, opaque, milky white, whorls 12, scarcely convex, or flattened; with numerous thick, sloping, rounded, smooth ribs; interstices small, inconspicuous, equalling the ribs in width; last whorl with the ribs scarcely obsolete at the periphery ; base smooth,

[^2]:    Zizyphinus legrandi. n.s. Z.t. abbreviato-conica, carneo-favescenti; anfractibus 6, planulatis,spiraliter densè canaliculato-liratis; ultimo anfractu angulato ; basi planulato, lineis impressis, alternantibus sculpta; apertura subquadrata ; labro acuto ; labio simplici. Alt et diam. 12.
    Z. shell abbreviately conical, fleshy yellow; whorls 6 , somewhat flattened; densely spirally canaliculately lirate; last whorl angulate, base flattened, sculptured with fine alternating

[^3]:    Dosinia mmacolata. n.s. D.t. suborbicularisubinflata; umbones rersus subattenuata, nirea, sulnitida ct sub lente eleganter irridescenti, umbonibus leviter cameola maculatis, coneentrice tenuiter striath ; striis sultillissime clegantissimeque decussata; area ligamenti angusté lanceolata; lunula parra, late cordata, impressa, medio carinuta, intus alla; sinu palliuri profundo, obtuse triangulato. Long. 20. Lat. 26.
